

How good is the invasion model? (h = 2w)

(A) calibration + AUC and (B) real-time prioritisation vs random – after Kraemer & Cauchemez 2017, Lancet Inf Dis, Fig 3

(A) Calibration: predicted vs observed invasion (h = 2w)

On the diagonal = calibrated probabilities; below = over-confident.

Bayes-M10-geo zone-weeks ● 1000 ● 2000 ● 3000 ● 4000

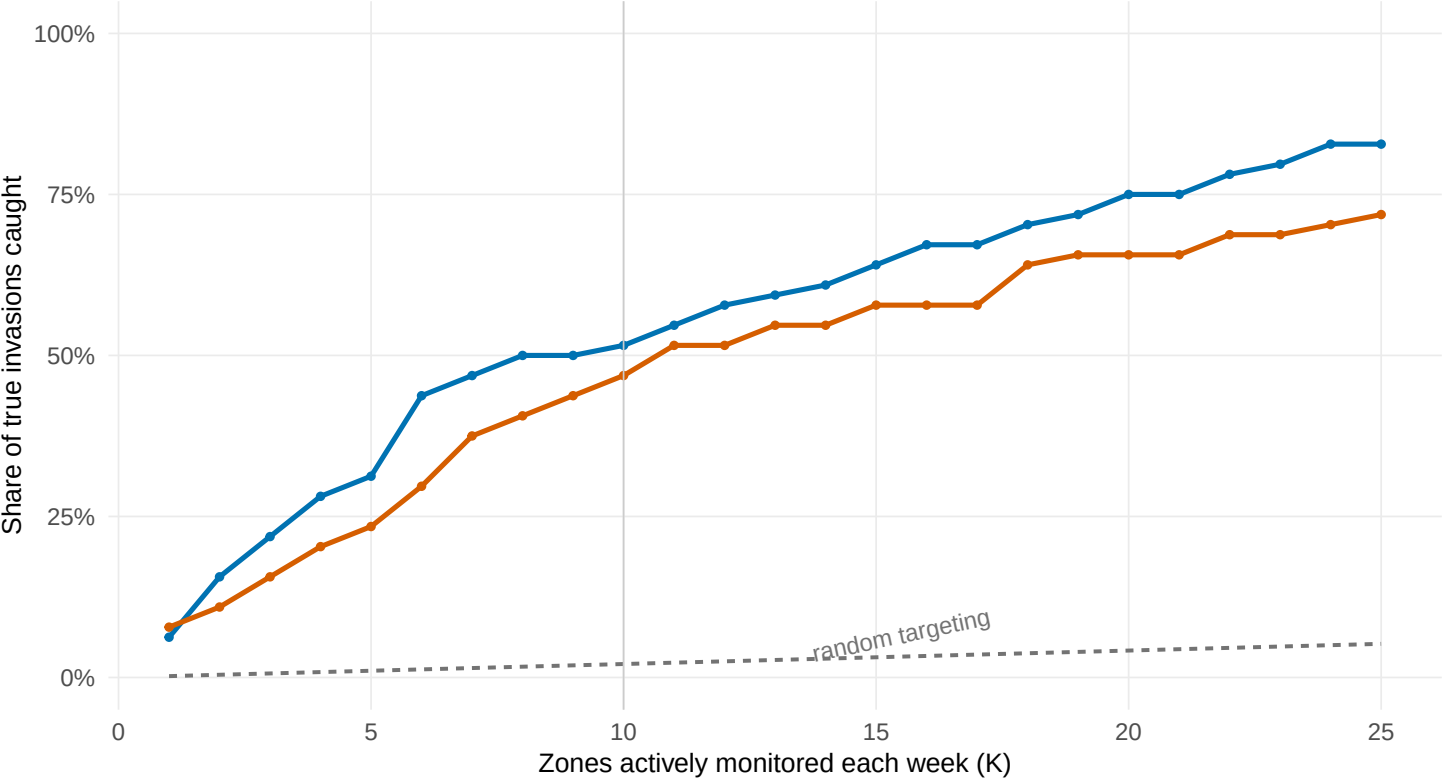

The 4.3% of at-risk zone-weeks we score >15%/week had a 19% observed invasion rate.

(B) Prioritisation: invasions caught vs random targeting

Share of true next-week invasions caught at a fixed weekly alert budget of K zones, pooled over LFO folds

Bayes-M10-geo Naive-epicentre-inflow

At a budget of K=10 zones/week, Bayes-M10-geo catches 52% of the next invasions vs 2% for random targeting (24.7x better).
